

# The inequality (condition) of Hadwiger.

G. A. Tsintsifas

Let  $F_0$  and  $F_1$  convex sets. We have defined "cutting number of  $F_0$  with respect (or relative) to  $F_1$ " every real number  $r$  so that the  $rF_1$  does not included in the interior of  $F_0$  and does not include in the interior the  $F_0$ . Let now an axis  $OX$  and  $O_1, A_1$  points of  $F_1$ . We suppose that  $\angle(OX, O_1A_1) = \phi$ . We understood that the cutting number  $r$  depends from the angle  $\phi$ . So we can denote by  $d(\phi)$  the width of the cutting numbers (see the paper about the cutting numbers in this blog). The Hadwiger condition is about the relation between the perimeters and the areas of two convex sets so that exist the possibility of a transposition of the one in the interior of the other. (By transposition we mean a displacement or an isometry, that is a transformation product of translations, rotations and symmetries). The continuity of the angle  $\phi$  assures us that the continuous function  $d(\phi)$  has extremities. We set

$$d_0 = d(\phi_0) = \min d(\phi)$$

Let now  $\rho_0 = \rho_{F_1}(F_0)$  the inradius of  $F_0$  relative to  $F_1$  and  $R_0 = R_{F_1}(F_0)$  for the angle  $\phi_0$ . That is

$$d_0 = [\rho_0, R_0]$$

## definition

We will define by Strong cutting number every real number of the interval  $d_0 = [\rho_0, R_0]$ . We denote  $r_0$ .

That is:

$$\rho_0 \leq r_0 \leq R_0$$

Hence, according the above, there is no transposition so that the  $r_0F_1$  includes or is including to  $F_0$ . Let us suppose that  $r_0 = 1$  that is the strong cutting number of  $F_0$  relative to  $F_1$  is the unity and that  $F_1$  has an angle equal to  $\theta$  with respect to constant axis. We know that the mixed area  $V(F_0, F_1)$  is a function of  $\theta$ . The integration of the relation

$$2V(F_0, F_1) \geq V(F_0) + V(F_1)$$

with respect  $\theta$  from 0 to  $2\pi$ , gives:

$$2. \int_0^{2\pi} V(F_0, F_1) d\theta \geq \int_0^{2\pi} [V(F_0) + V(F_1)]$$

or

$$2 \frac{L_0 L_1}{2} \geq 2\pi [V(F_0) + V(F_1)]$$

Therefore

$$L_0 \cdot L_1 \geq 2\pi [V(F_0) + V(F_1)] \quad (1)$$

hence, if for  $F_0$  and  $F_1$  is  $r_0 = 1$  (that is strong cutting number=1) then we will have the relation (1). Of course ,it is not correct the opposite.

The inequality (1) assures us that if

$$L_0 L_1 < 2\pi [V(F_0) + V(F_1)] \quad (2)$$

the the unit is not a strong number. that is will exist a transposition so that the  $F_1$  will be in the interior of  $F_0$  or the opposit.

The relation (2) is called inequality or condition o Hadwinger.

### Some applications

1. Let  $F_0, F_1$  convex sets in  $E^2$  and  $r_0$  strong cutting number of  $F_0$  to  $F_1$ .The relation (1) is

$$r_0 L_0 L_1 \geq 2\pi [V(F_0) + r_0^2 V(F_1)] \quad (3)$$

or

$$0 \geq 2\pi \cdot V(F_1) \cdot r_0^2 - L_0 \cdot L_1 \cdot r_0 + 2\pi \cdot V(F_0)$$

We now denote by  $\rho_0$  the strong inradius of  $F_0$  with respect  $F_1$  and by  $R_0$  the strong circumradius of  $F_0$  with respect of  $F_1$ . From (3) we easily we take.

$$\frac{L_0^2 \cdot L_1^2}{16\pi^2} - V(F_0) \cdot V(F_1) \geq \frac{V(F_1)^2 \cdot [R_0 - \rho_0]^2}{4} \quad (4)$$

Let  $t \notin d_0 = [\rho_0, R_0]$  For the sets  $F_0, tF_1$  the Hadwiger's condition is:

$$0 < 2\pi V(F_1) \cdot t^2 - L_0 \cdot L_1 \cdot t + 2\pi V(F_0)$$

the number  $t$  must be beetwin the roots of the equation

$$0 = 2\pi V(F_1) \cdot t^2 - L_0 \cdot L_1 \cdot t + 2\pi V(F_0)$$

that is:

$$t < \frac{L_0 L_1 - \sqrt{D}}{4\pi V(F_1)} \quad \text{and} \quad t > \frac{L_0 L_1 + \sqrt{D}}{4\pi V(F_1)}$$

where  $D = L_0^2 L_1^2 - 16\pi^2 V(F_0)(F_1)$ .

Hence, for

$$t = \frac{L_0 L_1 - \sqrt{D}}{4\pi V(F_1)} - \varepsilon$$

and for  $\varepsilon$  small the figure  $tF_1$  can insert in  $F_0$ . For  $\varepsilon \rightarrow 0$ , we finally see that there is

$$t \geq \frac{L_0 L_1 - \sqrt{D}}{4\pi V(F_1)}$$

so that the  $tF_1$  could be inside to  $F_0$ .

Exactly the same for

$$t \leq \frac{L_0 L_1 + \sqrt{D}}{4\pi V(F_1)}$$

we can displace  $F_1$  so that  $F_1$  include the  $F_0$ . For the convex figures  $F_0, F_1$  in the plane holds

$$L_0^2 L_1^2 \geq 2\pi \left[ L_1^2 V(F_0) + L_0^2 V(F_1) \right] \quad (5)$$

The proof is an easy application of the formula (1) for the  $F_0$  and  $F = \frac{L_0}{L_1} L_1$ . Indeed the convex figures  $F_0$  and  $F$  have the same perimeters, therefore we can use (1). that is

$$L_0 L_1 \geq 2\pi \left[ V(F_0) + V(F) \right]$$

or

$$L_0 \left( \frac{L_0}{L_1} L_1 \right) \geq 2\pi \left[ V(F_0) + V(F_1) \cdot \frac{L_0^2}{L_1^2} \right]$$

In the paper "The cutting Numbers" in this blog the relation (6) is

$$rV(F_0, F_1) \geq \frac{V(F_0) + r^2 V(F_1)}{2}$$

where  $r = r_{F_1}(F_0)$ .

We suppose that the  $F_0, F$  have the same breadth in the direction  $\theta$ , and  $F_0, F_1$  have Breadth  $B_0(\theta_1), B_1(\theta_1)$ . The figure  $F = \frac{B_0(\theta_1)}{B_1(\theta_1)} F_1$  has the same

breadth with  $F_0$  relative the direction  $\theta_1$  therefore the above for  $r = \frac{B_0(\theta_1)}{B_1(\theta_1)}$  is.

$$V(F_0, F_1)^2 - V(F_0)V(F_1) \geq \frac{\left[ B_1(\theta_1)^2 V(F_0) - B_0(\theta_1)^2 V(F_1) \right]^2}{4B_0(\theta_1)^2 B_1(\theta_1)^2} \quad (6)$$

Some interest has the application of the above for  $F_1 = U$  the unit circle.
