# Problems of plane Geometry. 

George Tsintsifas

## Problem1

Let $A B C$ be a triangle and the points $A^{\prime}, B^{\prime}, C^{\prime}$ are on the sides $B C, C A, A B$ respectively so that $B A^{\prime}=C B^{\prime}=A C^{\prime}$.
Prove that the incenters of the triangles $A B C, A^{\prime} B^{\prime} C^{\prime}$ are common, if and only if, the triangle $A B C$ is equilateral.
Solution
We consider the common incenter $O$ as the origin of the Cartesian system. We will denote on the plane of $A B C$ the vector $\overrightarrow{O M}$ by $M$. The sides of the triangles $A B C$ and $A^{\prime} B^{\prime} C^{\prime}$ are $a, b, c$ and $a^{\prime}, b^{\prime}, c^{\prime}$.
We know that the incenter of $A B C$ is the point $\frac{a A+b B=c C}{a+b+c}$. Therefore we will have.

$$
\begin{equation*}
\frac{a A+b B+c C}{a+b+c}=O \quad \frac{a^{\prime} A^{\prime}+b^{\prime} B^{\prime}+c^{\prime} C^{\prime}}{a^{\prime}+b^{\prime}+c^{\prime}}=O \tag{1}
\end{equation*}
$$

Let us suppose $B A^{\prime}=C B^{\prime}=A C^{\prime}=p$. We easily see that

$$
\begin{equation*}
A^{\prime}=\frac{p C+(a-p) B}{a}, \quad B^{\prime}=\frac{p A+(b-p) C}{b}, \quad C^{\prime}=\frac{p B+(c-p)}{c} \tag{2}
\end{equation*}
$$

Let G the barycenter of the triangle $A^{\prime} B^{\prime} C^{\prime}$, it is:

$$
\begin{equation*}
A^{\prime}+B^{\prime}+C^{\prime}=3 G \tag{3}
\end{equation*}
$$

We can easily see that: In a triangle, if the centroid coincides with the incenter, then the triangle must be equilateral.
That is if $G=O$ then the triangle $A^{\prime} B^{\prime} C^{\prime}$ is equilateral. If $G$ is not $O$ then the triangle $A^{\prime} B^{\prime} C^{\prime}$ is not equilateral.

From the above we conclude that the condition to be the triangle $A^{\prime} B^{\prime} C^{\prime}$ equilateral is:

$$
A^{\prime}+B^{\prime}+C^{\prime}=0
$$

hence from (2) have

$$
\begin{equation*}
a b c\left(A^{\prime}+B^{\prime}+C^{\prime}\right)=p b c C+c b(a-p) B+p a c A+a c(b-p) C+p a b B+a b(c-p) A=0 \tag{4}
\end{equation*}
$$

From (1) we have $A=-\frac{b B+c C}{a}$. We replace $A$ in (4) and we have after some Algebra

$$
\begin{equation*}
\left(b c(a-p)-p b c+a b p-b^{2}(c-p)\right) B+\left(p b c-p c^{2}+a c(b-p)-b c(c-p)\right) C=0 \tag{5}
\end{equation*}
$$

Relation (5) holds only for when coefficients of the vectors $B$ and $C$ are zero. That is

$$
\begin{align*}
& b c(a-p)-p b c+p a b-b^{2}(c-p)=0  \tag{6}\\
& p b c-p c^{2}+a c(b-p)-b c(c-p)=0 \tag{7}
\end{align*}
$$

From (6) and (7) we take

$$
\begin{equation*}
(a-b)(b-c)(c-a)=0 \tag{8}
\end{equation*}
$$

From (8) follows that the triangle $A B C$ is only isosceles. Let us suppose that $b=c$.That is for the triangle $A B C$ is $A B=A C$

$\operatorname{aFrom}(1)$ is: $a A+b B+b C=0$ that is $a A+b(2 D)=0$ where $A M$ is the altitude of the isosceles triangle $B A C$. But $2 \cdot|\overrightarrow{O D}|=|\overrightarrow{O A}|$ or $\mathrm{a}=\mathrm{b}$. that is $\mathrm{b}=\mathrm{c}$ and $\mathrm{b}=\mathrm{a}$ hence the triangle $A B C$ is equilateral

## comments

For the solution of the following problems we are using the same method Problem 2

The same us the problem 1 but here the centroids of the two triangles coincide.
So here we have

$$
A+B+C=0 \quad A^{\prime}+B^{\prime}+C^{\prime}=0
$$

We replace in (4) $A=-B-C$. The vectors $B, C$ are independent so their coefficients are zero.Finally we have

$$
b c+a b=2 a c \quad b c+a c=2 a b
$$

And from here $a=b=c$

## problem 3

The triangle $A B C$ is equilateral, $A^{\prime} B^{\prime} C^{\prime}$ is the inscribed triangle. Here the incenters coincide. We have to prove that the triangle $A^{\prime} B^{\prime} C^{\prime}$ is equilateral. Another problem of the same type is the following. The inscribed triangle $A^{\prime} B^{\prime} C^{\prime}$ in $A B C$ is equilateral. The incenters coincide. We prove that the triangle $A B C$ is equilateral. For the solution we can use the same method. But here there is also another one simple solution.

## Problem 4

The inequality of Pedoe
Let $A B C$ and $A^{\prime} B^{\prime} C^{\prime}$ two triangles. We denote by $a, b, c$ and $a^{\prime}, b^{\prime}, c^{\prime}$ their sides and $E, E^{\prime}$ the area. We call the quantity of Pedoe the symmetrc (for $\left.a, b, c, a^{\prime}, b^{\prime}, c^{\prime}\right)$ formula

$$
P=\sum a^{2}\left(-a^{\prime 2}+b^{\prime 2}+c^{\prime 2}\right)
$$

The inequality of Pedoe is:

$$
\begin{equation*}
P \geq 16 E E^{\prime} \tag{9}
\end{equation*}
$$

For the proof we will use the Leibnitz s formula

$$
\begin{equation*}
\sum_{1}^{n} m_{i} \cdot p A_{i}^{2}=m \cdot p G^{2}+\frac{1}{m} \sum_{i>j} m_{i} m_{j} \cdot a_{i j}^{2} \tag{10}
\end{equation*}
$$

where $A=\left(A_{1}, A_{2}, \ldots . A_{n}\right)$ is an simplex, $G=\left(m_{1}, m_{2}, \ldots \ldots . m_{n}\right)$ the centroid, that is
$G=\frac{\sum m_{i} A_{i}}{\sum m_{i}}$. and $\mathrm{p} \in R^{n}$ and $m=\sum m_{i}$.

For the triangles $A B C$ and $A^{\prime} B^{\prime} C^{\prime}$, we suppose

$$
G\left(m_{1}, m_{2}, m_{3}\right)=G\left(a^{2}\left(-a^{\prime 2}+b^{2}+c^{2}\right), b^{2}\left(a^{2}-b^{2}+c^{2}\right), c^{2}\left(a^{2}+b^{2}-c^{2}\right)\right)
$$

and $\mathrm{p}=\mathrm{O}$ the circumcenter of $A B C$. We will have

$$
\begin{gathered}
R^{2}\left[\sum a^{2}\left(-a^{\prime 2}+b ;^{2}+c^{\prime 2}\right)\right]^{2}= \\
=\sum a^{2} b^{2} c^{2}\left(a^{\prime 2}-b^{\prime 2}+c^{\prime 2}\right)\left(a^{2}+b^{\prime 2}-c^{2}\right)= \\
=a^{2} b^{2} c^{2}\left[\sum a^{4}-\left(b^{\prime 2}-c^{\prime 2}\right)^{2}\right]^{2}=
\end{gathered}
$$

or

$$
=R^{2}\left[\sum a^{2}\left(-a^{\prime 2}+b^{\prime 2}+c^{\prime 2}\right)\right]^{2} \geq a^{2} b^{2} c^{2} 16 E^{2}
$$

or

$$
\sum a^{2}\left(-a^{\prime 2}+b^{2}+c^{\prime 2}\right) \geq \frac{4 E R \cdot 4 E^{\prime}}{R}=16 E E^{\prime}
$$

## problem 5

Let $A B C$ be atriangle and $P$ an interior point. We easily prove that there is a triangle wit sides $a A P, b B P, c C P$. where by $A P, B P, C P$ we denote the str. line segments $A P, B P, C P$. We construct the triangle $A P P^{\prime}$ similar to $A P B$

The triangles $A P P^{\prime}$ and $A B C$ are similar. The triangle $P P^{\prime} C$ has sides $P P^{\prime}=\frac{a}{c} B P$ and $P^{\prime} C=\frac{b}{c}$
The triangles $(a A P, b B P, c C P)$ and $c \cdot\left(P P^{\prime} C\right)$ are similar.
The angles are

$$
\begin{gathered}
\angle P C-\angle A=\angle P C P^{\prime} \text { opposite of } a A P \\
\angle C P A-\angle B=\angle C P P^{\prime} \text { opposite of } b B P
\end{gathered}
$$

$\angle A P B-\angle C=\angle P P^{\prime} C$ opposite of $c C P$
A second triangle $A^{\prime} B^{\prime} C^{\prime}$ has sides $a^{\prime}, b^{\prime}, c^{\prime}$. we determine the point $P$ in the triangle $A B C$ so that:

$$
\begin{equation*}
\frac{a A P}{a^{\prime}}=\frac{b B P}{b^{\prime}}=\frac{c C P}{c^{\prime}}=m \tag{11}
\end{equation*}
$$

Cos. theorem in the triangle $B P C$ gives:

$$
a^{2}=m^{2}\left[\frac{b^{\prime 2}}{b^{2}}+\frac{c^{\prime 2}}{c^{2}}-\frac{2 b^{\prime} c^{\prime}}{b c} \cos \left(A+A^{\prime}\right)\right]
$$

After some Algebra we take

$$
a^{2}=\frac{m^{2}}{b^{2} c^{2}}\left[b^{\prime 2} c^{2}+c^{\prime 2} b^{2}-\frac{\left(b^{2}+c^{2}-a^{2}\right)\left(b^{\prime 2}+c^{\prime 2}-a^{\prime 2}\right)}{2}+8 E E^{\prime}\right]
$$

Consequently

$$
a^{2}=\frac{m^{2}}{b^{2} c^{2}}\left[\frac{P}{2}+8 E E^{\prime}\right]
$$

where P is the quantity Pedoe. and

$$
\begin{equation*}
m=\frac{a b c}{\left[\frac{P}{2}+8 E E^{\prime}\right]^{1 / 2}} \tag{12}
\end{equation*}
$$

From the above we can find new triangle inequalities of Pedoe s style. For example taking in mind the inequality $a a^{\prime}+b b^{\prime}+c c^{\prime} \geq 4 \sqrt{3 E E^{\prime}}$ we easily find that

$$
\sum a^{2} A P \geq \frac{4 a b c}{P^{1 / 2}} \sqrt{3 E E^{\prime}}
$$

Here we can prove anothere important inequality. The inequality of O. Bottema. that is for two triangles $A B C$ and $A^{\prime} B^{\prime} C^{\prime}$ and the internal points $P$ and $P^{\prime}$ holds

$$
a^{\prime} A P+b^{\prime} B P+c^{\prime} C P \geq\left(P / 2+8 E E^{\prime}\right)^{1 / 2}
$$

We need n elementary inequality, for the triangle $A B C$ and two internal points $P$ and $M$ we have

$$
a \cdot A P \cdot A M+b \cdot B P \cdot B M+C . C P . C M \geq a b c
$$

From (11) and (12 and the above) follows Bottema s inequality the Apollonius circles, the isodynamic centers
It is known that the Apollonius circles have a common chord $P P^{\prime}$. The points $P, P^{\prime}$ are called Isodynamic points. One of the two points let the $P$ is interior in the triangle $A B C$. We easily see that

$$
\frac{A P}{b c}=\frac{B P}{a c}=\frac{C P}{a b}
$$

so we can take

$$
\frac{a A P}{a b c}=\frac{b B P}{a b c}=\frac{c C P}{a b c}
$$

Hence the triangle ( $a A P, b B P, c C P$ ) is equilateral . Therefore we have:

$$
\angle B P C=60^{\circ}+A \quad \angle C P A=60^{\circ}+B \quad \angle A P B=60^{\circ}+C .
$$

we also can prove that the feeds of $P$ on the sides of $A B C$ are the vertices of equilateral triangle, the minimum inscribed trianle in the $A B C$.
